

FirstPROOF v2.1.3 Release Notes

The 2.1.3 release of FirstPROOF is a critical update for the Mac, containing a number of bugs fixes; mainly for correct operation under OSX 10.4 (Tiger).

1. Mac Changes and Fixes:

1. Some of the file APIs we used caused problems under OSX 10.4 (Tiger). These have been modified so that they no longer cause a crash.
2. A problem with obtaining the Lock File under OS9 when Outputting has been fixed.
3. The security system could still occasionally lose its Activation Key requiring that it either be re-entered or worse still that FirstPROOF be re-activated; the previous fix in this area missed out one possible case. This has now been completely fixed.
4. The memory model used under OSX has been fixed; previously it was limited to caching only 20M or thereabouts of view data. This has now been increased to 75% of available physical memory. As a result, viewing of (large) images should be substantially faster.
